

# DETROIT DARK RED

## Garden Beet

### OUTSTANDING QUALITIES

- ◆ WARM SEASON PRODUCTION
- ◆ DEEPER COLOUR AND SMOOTHER SKIN THAN OTHER DETROIT DARK RED SELECTIONS
- ◆ REFINED CROWN AND TAP ROOT

**Detroit Dark Red** is a superb Detroit selection, offering deeper colour, smoother skin and a more refined taproot and crown attachment than traditional Detroit selections. The slow bolting habit and good round shape even at early development, makes **Detroit Dark Red** suitable for bunching, topping and home garden use in temperate and subtropical regions. **Detroit Dark Red** has intermediate resistance to Leaf spot (Cb).

### SPECIAL VARIETAL REQUIREMENTS

- Suggested for warm season production
- Contact area representative for a sowing guide

CHARACTERISTIC*	DETROIT DARK RED
KIND	Garden beet selection ( <i>Beta vulgaris</i> L. subsp. <i>vulgaris</i> var. <i>conditiva</i> Alef.)
MATURITY	70 - 80 days for warm season production
SEASON	Warm
ROOT SHAPE	Round
CROWN SIZE	Medium
SMOOTHNESS	Smooth
INTERNAL COLOUR	Deep red with light zoning
ZONING	Light
SUGAR CONTENT	Medium
TOP HEIGHT	35 – 40 cm
LEAF HABIT	Semi-erect
LEAF COLOUR AND GLOSS	Dark green / matte
PURPLE IN LEAF (BETALIN PIGMENT)	Moderate
BOLTING HABIT	Slow to bolt
DISEASE REACTION (SCIENTIFIC)	<b>Intermediate resistance:</b> <i>Cercospora beticola</i> (Cb)
PLANT POPULATION	450 000 - 550 000 seeds per ha for normal roots
UNIFORMITY	Good
MARKET USE	Fresh market, processing and home garden
SPECIAL FEATURES	High yield, heat tolerant, refined round shape

\* Characteristics given are affected by production methods such as soil type, nutrition, planting population, planting date and climatic conditions. Please read disclaimer.

**Disclaimer:** This information is based on our observations and/or information from other sources. As crop performance depends on the interaction between the genetic potential of the seed, its physiological characteristics, and the environment, including management, we give no warranty express or implied, for the performance of crops relative to the information given nor do we accept any liability for any loss, direct or consequential, that may arise from whatsoever cause. Please read the Sakata Seed Southern Africa (Pty) Ltd Conditions of Sale before ordering seed.

**Resistance:** is the ability of a plant variety to restrict the growth and development of a specified pest or pathogen and/or the damage they cause when compared to susceptible plant varieties under similar environmental conditions and pest or pathogen pressure. Resistant varieties may exhibit some disease symptoms or damage under heavy pest or pathogen pressure (HR = High resistance, IR = Intermediate resistance).

**Recent version:** Kindly contact Sakata or Area Representative for the most recent version of this Technical Bulletin.

## GENERAL TIPS FOR BEET PRODUCTION

### Fertiliser requirements

#### Macro-nutrients

Soil tests are the most accurate guides to Fertiliser requirements. Soil should be tested at least every two to three years, however many farmers prefer to check this every season. Nitrogen does not accumulate in soil over time, so it should be applied annually. A representative soil sample of the whole field should be taken for more accurate results.

Good management practices are essential if optimal fertiliser responses are to be realized. These practices include; use recommended varieties, selection of appropriate soils, good weed control, disease and insect control, good seed bed preparation, proper seeding methods and timely harvest.

#### Lime

Lime applications should be made when the soil pH is 5.8 or below, or when calcium levels are below 7 meq (milli equivalent) Ca/100 g soil.

Lime should be mixed into the soil several weeks before planting and preferably the previous autumn. A lime application is effective over several years.

For acid soils low in magnesium (less than 1.0 meq Mg/100 g soil), 2.25 tonnes per hectare of dolomitic lime can be used as a Mg-source. Dolomite and ground limestone have about the same ability to neutralise soil acidity.

#### Nutrient Deficiencies

**Nitrogen (N)** – Purpling or yellowing of older leaves usually accompanied by retarded growth of roots and plants. Variation from purple to yellow is associated with temperatures.

**Phosphorus (P)** – Leaf blade unusually flat. Prominent purple venation even to finest veins, leading to a bronze look. New leaves are purple, small and erect.

**Sulphur (S)**: Young leaves are narrow, very brittle and erect. They appear yellow and are densely speckled with purple spots, which eventually coalesce, making whole leaf purple.

**Molybdenum (Mo)**: Patches on the leaf die and become papery.

**Potassium (K)**: Old leaves become limp and die back from tip.

**Calcium (Ca)**: Young leaves have purple-black, hooked tips, which later die and exhibit leaf roll.

**Magnesium (Mg)**: Interveinal chlorosis (yellowing) with reddish tinting on older leaves. At times chlorosis is not observed but interveinal red mottling. Later, brown blisters with purple edges are seen on intermediate aged leaves. If Mg levels are low at more mature growth stage, a pronounced convex bubbling of the leaf lamina between the veins makes midrib appear deeply recessed.

**Iron (Fe)**: Young leaves appear bleached while older leaves have a reddish tint.

**Manganese (Mn)**: Leaves triangular in shape with margins curled inward and severe interveinal speckling. Older leaves are chlorotic and fade to reddish colour with brown interveinal tissue. Roots reduced in size.

**Boron (B)**: Canker-scattered black lesions in the flesh of the root, sometimes with large black areas on root surface. Lack of moisture aggravates boron deficiencies. Boron should not be banded; instead, it should be applied evenly over the field.

#### Disease resistance definition

**Resistance**: is the ability of a plant variety to restrict the growth and development of a specified pest or pathogen and/or the damage they cause when compared to susceptible plant varieties under similar environmental conditions and pest or pathogen pressure. Resistant varieties may exhibit some disease symptoms or damage under heavy pest or pathogen pressure. Two levels of resistance are defined:

**High/standard resistance (HR)**: plant varieties that highly restrict the growth and development of the specified pest or pathogen under normal pest or pathogen pressure when compared with susceptible varieties. These plant varieties may, however, exhibit some symptoms or damage under heavy pest or pathogen pressure.

**Moderate/intermediate resistance (IR)**: plant varieties that restrict the growth and development of the specified pest or pathogen, but may exhibit a greater range of symptoms or damage compared to resistant varieties. Moderately/intermediately resistant plant varieties will still show less severe symptoms or damage than susceptible plant varieties when grown under similar environmental conditions and/or pest or pathogen pressure.
